

Devon Yuan

+1 (236) 458-2221 | devon.yuan@outlook.com | [LinkedIn](#) | [GitHub](#) | [Personal Website](#) (Scan the QR Code!)

Relevant Coursework: Data Structures & Algorithms, Software Construction, Computer Systems

TECHNICAL SKILLS

Languages | Go, Python, TypeScript/JavaScript, SQL, Java, C++, R

Frameworks | Golang-Migrate, Electron, TanStack Query, React/NextJS, TailwindCSS, Express.js, chi, FastAPI, Playwright, React 3F

Developer Tools and Operating Systems | Git, GitHub CLI, Docker, Visual Studio Code, pgAdmin4, Linux Mint, MacOS, Windows

Project Leadership | GitHub Issues, GitHub Projects, Branches, PR reviews, GitHub Workflows, System Design/Architecture

Cloud | Azure, GCP, AWS, Supabase, Railway, Render, Vercel

AI | Prompt Engineering, APIs, Agentic Workflows, using Copilot, Claude Code, Cursor, Devin, Ollama, LM Studio

WORK EXPERIENCE

Innershell Solutions Corp.

Software Development Intern (Contract)

07/2026 – Present

Edmonton (Remote)

- Worked on [PerksWyse](#), a loyalty and payment platform for the plasma donation medical industry (life sciences).
- Rebuilt the backend, originally a no-code platform (Xano) using Go, resolving the proprietary lock-in of Xano.
- Ported 43 API endpoints and 14 database tables to the new platform with zero data loss.
- Containerized the backend using Docker Compose, streamlining end-user installation and deployment.
- Rebuilt and expanded the test suite to validate the migration, with 594 Playwright tests (192 API, 402 end-to-end).
- Enhanced the system with agentic features that allow end-users to configure complex rules and validate their configuration with their own API key and choice of models.
- Configured an AI coding agent on the codebase, developing agentic instructions to support ongoing development.

Project Lead Intern (Contract).

- Served as the project lead by drafting and implementing tickets with a detailed template, debugging the app, configuring agentic instructions, and following an "Impact Analysis" approach.
- Automated repetitive portions of the development workflow using GitHub CLI scripts, replacing repetitive manual GitHub operations with repeatable command-line processes, introducing a fully agentic workflow.
- Designed and implemented a GitHub App project aimed at reducing manual compliance overhead in regulated software development by embedding audit-trail and approval-gate capabilities directly into GitHub's Issue and PR workflows.
- Captures snapshots of GitHub issues and freezes the content to maintain accountability.

PROJECTS

Tether - StormHacks 2026 | TypeScript, React, Electron, Tailscale, MCP Servers

- Built a desktop application that allows users to share the capabilities of their locally running MCP servers with their teammates.
- Includes a streamlined process of adding local MCP servers by adding both HTTP URLs and local commands (stdio).
- Allows small teams of developers who are working at the same time to host and share their MCP capabilities without requiring setup on every single machine.
- Prevents small teams from paying an expensive cloud bill to host online MCP servers, providing teams a higher level of autonomy, data privacy, and security.
- Uses Tailscale to securely connect to clients via VPN, and allows the host themselves to approve or deny connections.
- Includes real-time logging of CPU, memory, calls per minute, latency, denied requests, all for each connected device, and each locally running server, stored in SQLite. Additionally includes both a row-by-row view of the connected machines and a graphical tree view showing the host and all clients, differentiating connected, offline, and disconnected machines.

OmniDrive – Unified Storage Pooler | FastAPI, React, Electron, SQLite

- Built a desktop application that unifies Google Drive and OneDrive into a single virtual filesystem, allowing users to browse and manage files across both providers through one interface.
- Remains functional even when Google Drive and OneDrive are still used independently, maximizing users' convenience.
- Integrated the Google Drive API and Microsoft Graph Files API into a FastAPI backend to authenticate with and perform file operations across two independent cloud storage systems.
- Designed a recursive virtual file system in backend memory and persisted file routing metadata in SQLite, translating provider-specific folder structures into a unified representation for the application.

CourseFlow | TypeScript, React, Electron

- Built a productivity app that ingests Canvas iCal feeds to centralize course deadlines and address the limitations of Canvas's built-in to-do list with more flexible task management.
- Completed the MVP with deadline sub-tasks, notes, progress tracking, and standalone notetaking, giving students more control over how they organize and track coursework.

Visualize Mechanics | FastAPI, React, 3Fiber, Electron

- Built a desktop application that processes basic physics questions and classifies them into a scenario, then produces a 3D rendering of the question.
- Includes a worked solution and a live variables tab to view variables of the question in real time.
- Allows users struggling to grasp basic physics concepts to understand the problems visually and view them from all angles.
- Uses BYOK with the NVIDIA NIM API (The choice of vision and reasoning models themselves were picked through several iterations to find the ideal balance between speed and intelligence).

Data Analysis Chatbot | FastAPI, React, PostgreSQL, Ollama

- Built a full-stack data analysis application using FastAPI and React that allows users to query datasets using natural-language prompts and receive programmatically generated analyses, effectively combatting hallucination.
- Integrated Gemini API to convert natural-language questions to Pandas code, then executed and captured the generated code's output against the user's dataset rather than relying on the LLM to perform numerical calculations directly. Used Ollama during early local development.
- Implemented a cloud deployment architecture with FastAPI hosted on Railway, React hosted on Render, and PostgreSQL and object storage managed through Supabase, enabling the application to operate as a deployed web servi

EDUCATION

BSc. Major in Computer Science
The University of British Columbia

2030 (Anticipated)
Vancouver
